

CI is code to implement into github that runs whenever we change code/push or commit.

It will run when triggered and go through all the code and make sure it works as intended and doesn't break the code. It's basically integration testing in the background without effort to ensure the code will run.

It needs the coders to commit often to ensure it all works together!

CI will be implemented in our document via GITHUB actions and will include tests for each commit

When code is implemented, the written code will run all the tests to ensure the code is running as it should

Make sure of declaration all of the methods that you want to test w CI
